

Toward zero-power ICT

Luca Gamaitoni

NiPS Laboratory, University of Perugia

March 5th, 2015 - EPFL

Plan of the presentation

- 1) Some motivations
- 2) Some modeling
- 3) Some considerations
- 4) Some conclusions

Some motivations

A growing number of people accepted to join the so-called internet-of-things scenario

Before this scenario becomes a reality the device powering issue needs to be addressed and solved.

The challenge of efficient management of energy is a key aspect to consider in computing systems, especially for applications in smart sensors and Internet of Things devices.

European Commission **Workshop** on “Energy-Efficient Computing Systems, dynamic adaptation of Quality of Service and approximate computing”. Nov. 27 2014 - Brussels

Energy required to operate the portable devices

We need to bridge the gap by acting on both arrows

Energy available from portable sources

Some modeling

The device powering issue:

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

We consider devices at MEMS scale and below

We consider “ICT devices”: i.e. devices mainly devoted to computing task

An **ICT device** is an info-thermal machine that inputs **information** and **energy** (under the form of work), processes both and outputs information and energy (mostly under the form of heat).

Some interesting questions:

Why all the energy ends up in heat? What does it mean “energy dissipation”? Can be avoided?

What is the role of information? Is this a physical quantity that affects the energy transformations?

We need a physical model...

Two physical systems:

They transform energy

They have many d.o.f. (presence of fluctuations)

They are operated in a changing environment

~~Thermodynamics~~

~~Statistical mechanics~~

Non-equilibrium statistical mechanics

In this framework we can describe the device behavior in terms of few relevant d.o.f. via a procedure called “adiabatic elimination” or “coarse graining approach”: we exchange the dynamics of a *not small isolated system* with *small not isolated system*.

Two physical systems whose dynamical behavior can be described in the framework of non-equilibrium statistical mechanics.

Langevin equation approach

If $F_{ext} \gg \zeta$ then the thermal noise contribution can be ignored

$$m\ddot{x} = -\frac{dU(x,t)}{dx} - \gamma\dot{x} + \zeta_z$$

Two physical systems whose dynamical behavior can be described in the framework of non-equilibrium statistical mechanics.

Langevin equation approach

Two physical systems whose dynamical behavior can be described in the framework of non-equilibrium statistical mechanics.

Langevin equation approach

(example from vibration harvester)

$$m\ddot{x} = -\frac{dU(x)}{dx} - \gamma\dot{x} - c(x, V) + \zeta_z + \zeta$$

$$\dot{V} = F(\dot{x}, V)$$

$$\langle \zeta(t) \zeta(0) \rangle = 2 K_B T \gamma \delta(t)$$

Vibration Energy Harvesting: Linear and Nonlinear Oscillator Approaches, Gamaitoni, Luca, Vocca Helios, Neri Igor, Travasso Flavio, and Orfei Francesco , Sustainable Energy Harvesting Technologies - Past, Present and Future, InTech ed. (2011)

Two physical systems whose dynamical behavior can be described in the framework of non-equilibrium statistical mechanics.

Langevin equation approach

Two physical systems whose dynamical behavior can be described in the framework of non-equilibrium statistical mechanics.

Langevin equation approach

(example from a digital binary switch)

$$m\ddot{x} = -\frac{dU(x)}{dx} - \gamma\dot{x} + F_{sw} + \zeta$$

ζ

$\zeta(t) \quad \zeta(0) = 2 K_B T \gamma \delta(t)$

The equation is a Langevin equation for the position x . It includes the mass m , damping coefficient γ , external force F_{sw} , and a stochastic force ζ . The term $\zeta(t)$ represents the fluctuating force, and its average value $\zeta(0)$ is given by the expression below it, which is related to the thermal energy $K_B T$.

Transducer

Langevin equation approach

$$m\ddot{x} = -\frac{dU(x,t)}{dx} + \zeta_z - \gamma\dot{x} + \xi$$

ICT
device

This is a stochastic dynamics whose solution $x(t)$ appears like

Probability density $P(x,t)$.

$P(x,t)dx$ represents the probability for the observable x to be in $(x, x+dx)$.

$P(x,t)$ is a deterministic quantity and its time evolution can be described in terms of the associated Fokker-Planck equation.

Some considerations

The device powering issue:

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

An **ICT device** is an info-thermal machine that inputs **information** and **energy** (under the form of work), processes both and outputs information and energy (mostly under the form of heat).

YES

A computing device....

Is it possible to operate a binary (digital) computing device
with zero energy energy expenditure ?

a binary (digital) computing device

How does the binary (digital computation) work?

In modern computers the information is processed via networks of logic gates that perform all the mathematical operations through assemblies of basic Boolean functions. E.g. the NAND gate that due to its universal character can be widely employed to be networked in connected networks in order to perform any other logic functions.

I ₁	I ₂	O
0	0	0
0	1	0
1	0	0
1	1	1

Logic gates and switches

In a practical computer, the logic gate function is realized by some material device. The bit value is represented by some physical entity (signal) like electric current or voltage, light intensity, magnetic field,...etc.

Modern logic gate devices are made by assembling more elementary units: i.e. the **transistors**.

A transistor is an electronic device that here performs the role of a **switch** by letting or not-letting the electric current go pass through.

Es: the NAND gate with 2 transistor

Switches based on capacitors

$$E_{sw} = CV^2$$

Fig. 2. Device and circuit capacitance as a central concept of microelectronics.

$$E_{sw} = CV^2$$

$$P = \alpha E_{sw} f = \alpha C V^2 f$$

Minimum Energy of Computing, Fundamental Considerations, L. Victor Zhirnov, Ralph Cavin and Luca Gammaitoni

ICT - Energy

The present trend...

Research directions and challenges in nanoelectronics
R. K. Cavin¹, V. V. Zhirnov, D. J. C. Herr¹, Alba Avila and J. Hutchby, 2006

Thus, the search for alternative switches is presently very active.

To take on this grand challenge, the **Nanoelectronics Research Initiative** (NRI) (nri.sra.org) was formed in 2004 as a consortium of Semiconductor Industry Association (SIA) (www.sia-online.org) companies to manage a university-based research program as part of the Semiconductor Research Corporation (SRC) (www.sra.org).

ICT - Energy

Question:

Is there a fundamental physical limit to the minimum energy needed to switch?

There is no general agreement on the answer... and present limits are associated with charge based computation.

The Physics of switches

In order to describe the physics of a switch we need to introduce a **dynamical model** capable of capturing the main features of a switch.

The two states, in order to be dynamically stable, are separated by some energy barrier that should be surpassed in order to perform the switch event.

This situation can be mathematically described by a second order differential equation like:

$$m\ddot{x} = -\frac{d}{dx}U(x) - m\gamma\dot{x} + F$$

The Physics of switches

According to this model if we want to produce a switch event we need to apply an external force F capable of bringing the particle from the left well (at rest at the bottom) into the right well (at rest at the bottom).

Clearly this can be done in more than one way.

As an example we start discussing what we call the **first procedure**: a three-step procedure based on the application of a **large and constant force** $F=F_0$, with $F_0 > 0$

We can ask what is the minimum work that the force F has to perform in order to make the device switch from 0 to 1 (or equivalently from 1 to 0).

The work is computed as:

$$L = \int_{x_1}^{x_2} F(x) dx \quad \text{Thus } L = 2 F_0$$

The Physics of switches

Is this the minimum work?

Let's look at this other procedure (**second procedure**):

The only work performed happened to be during step 3 where it is readily computed as $L_1 = 2 F_1$. Now, by the moment that $F_1 \ll F_0$ we have $L_1 \ll L_0$

The Physics of realistic switches

This analysis, although correct, is quite naïve, indeed. The reason is that we have assumed that the work performed, no matter how small, is completely dissipated by the frictional force.

In order to be closer to a reasonable physical model we need to introduce a fluctuating force and thus a Langevin equation:

$$m\ddot{x} = -\frac{d}{dx}U(x) - m\gamma\dot{x} + \xi(t) + F$$

The relevant quantity becomes the probability density $P(x,t)$ and

$$p_0(t) = \int_{-\infty}^0 P(x,t)dx \quad \text{and} \quad p_1(t) = \int_0^{+\infty} P(x,t)dx$$

Represent the probability for our switch to assume “0” or “1” logic states

This calls for a reconsideration of the equilibrium condition

The Physics of realistic switches

In this new physical framework we have to do with exchanges of both work and heat (constant temperature transformation approximation).

Thus we have to take into account both the exchanges associate with work and the changes associated with entropy variation.

Entropy here is defined according to Gibbs:

$$S = -K_B \sum_i p_i \log p_i$$

Based on this new approach let's review the previous procedure:

The Physics of realistic switches

Based on this new approach let's review the previous procedure:

step 1

step 2

step 3

step 4

step 5

we observe a change in entropy:

$$S_1 = S_5 = -K_B \ln 1 = 0 \quad S_2 = -K_B (\frac{1}{2} \ln \frac{1}{2} + \frac{1}{2} \ln \frac{1}{2}) = K_B \ln 2.$$

The Physics of realistic switches

Based on these considerations we can now reformulate conditions required in order to perform the switch by spending zero energy:

- 1) The total work performed on the system by the external force has to be zero.
- 2) The switch event has to proceed with a speed arbitrarily small in order to have arbitrarily small losses due to friction.
- 3) The system entropy never decreases during the switch event.

Is it possible?

Yes... at least in principle...

FUTURE & EMERGING TECHNOLOGIES

Operating ICT basic switches below the Landauer limit

Magnetic nano dots

Single cylindrical element of permalloy (NiFe) with dimensions $50 \times 50 \times 5 \text{ nm}^3$

Entropy changes

Entropy stays constant

The device powering issue:

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

The device powering issue:

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

Clearly this energy is obtained from the ambient...

The device powering issue:

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

$$E_e = E_i - C$$

Question: can we make $C = 0$?

C is the energy dissipated during the transformation.

$$m\ddot{x} = -\frac{dU(x,t)}{dx} + \zeta_z - \gamma\dot{x} + \zeta$$

$C=C(\gamma)$ and γ is associated with the relaxation to equilibrium and depends on the characteristics of the device/material.

The device powering issue:

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

C

is the energy dissipated during the transformation.

$$m\ddot{x} = -\frac{dU(x,t)}{dx} + \zeta_z - \gamma\dot{x} + \zeta$$

C

The usual solution is to go very slow, i.e. to minimize \dot{x}

Good news: In principle there is no physical law that forbids to make $C = 0$

Bad news: This might affect the power we can use in the device

$C=C(\gamma)$ can be a function of time and change with the dissipation process.

Viscous damping, thermo-elastic damping, structural damping, ...

Generalized Langevin equation

$$m\ddot{x} = -\frac{dU(x,t)}{dx} + \zeta_z - \int_{-\infty}^t \gamma(t-\tau) \dot{x} d\tau + \zeta$$

The device powering issue:

$$m\ddot{x} = -\frac{dU(x,t)}{dx} + \zeta_z - \gamma\dot{x} + \zeta$$

- 1) How much energy is needed to power a device ?
- 2) Where does the device get the needed energy ?

Finally, the role of the potential energy $U(x,t)$

Beyond the linear oscillator approach

$$U(x) \neq \frac{1}{2}ax^2$$

$$U(x) = \frac{1}{2}k_e x^2 + (Ax^2 + B\Delta^2)^{-3/2}$$

Next issue Jul 15th 2015

Take-home message:

Focusing only on energy harvesting produces misconception.

The focus should be on energy transformation processes.

Both ends of the gap should be addressed if we want to move from labs to market.

What future for the subject of **energy harvesting / autonomous devices** ?

Bright!

The problem of powering small (and not so-small) autonomous devices has been already addressed and solved by nature. There is plenty of devices that process information (and actuate) while transforming energy from low entropy sources into heat.

None of them carries disposable batteries !
